## 2.2 Steps to train a simple neural network

- Collect and preprocess the data: this includes data cleansing, formatting the data to have suitable data type and splitting these data into training and test sets.
- Define the model: Next, we must define the neural network architecture. This will include choosing the number of layers, the number of nodes in each layer, and the activation functions

to use. Usually for classification problems the architecture is composed of : - A scaling layer - Tow perceptron layers - A probablistic layer

- Compile the model: After defining the model, you will need to compile it with a loss function, an optimizer, and any metrics that need to be tracked
- Train the model: train the model on the training data. This will involve providing the model with the training data and allowing it to learn the relationships between the input features and the target variables.
- Evaluate the model: After training, we need to evaluate the model's performance on the test data. This will give us a sense of how well the model is able to generalise to unseen data. For example we can switch between LogSoftMax, NLLLoss and Cross Entropy to check the difference in performance.
- Fine-tune the model: Depending on the results of the evaluation, we may want to adjust the model's architecture or hyperparameters to improve its performance. This process is known as fine-tuning.
- Make predictions: Finally, we can use the trained model to make predictions on new data.

### 2.3 Code example for train and testing a simple network

```
from keras.models import Sequential
from keras.layers import Dense
```

#### 2.3.1 define the model

```
model = Sequential()
model.add(Dense(10, input_dim=8, activation='relu'))
model.add(Dense(1, activation='sigmoid'))
```

### 2.3.2 compile the model

```
model.compile(loss='binary crossentropy', optimizer='adam', metrics=['accuracy'])
```

### 2.3.3 fit the model to the training data

```
model.fit(X_train, y_train, epochs=10, batch_size=32)
```

#### 2.3.4 evaluate the model on the test data

```
loss, accuracy = model.evaluate(X_test, y_test, batch_size=32)
print('Test loss:', loss)
print('Test accuracy:', accuracy)
```

The input features and target variables for the training data in this example are X train and y train, while the input features and target variables for the test data are X test and y test. The model consists of two layers: an output layer with one node and a hidden layer with ten nodes. The output layer makes use of the sigmoid activation function, whereas the hidden layer makes use of the relu activation function. The binary crossentropy loss function and Adam optimizer are used in the model's construction, and it is trained using stochastic gradient descent with a batch size of

32 on the training set of data. The model is then assessed using the test data, and the accuracy and loss are printed.

## 3 Q3

```
[27]: from sklearn import datasets, metrics
  from sklearn.model_selection import train_test_split
  import numpy as np

# Laoding the digits dataset
  digits = datasets.load_digits()

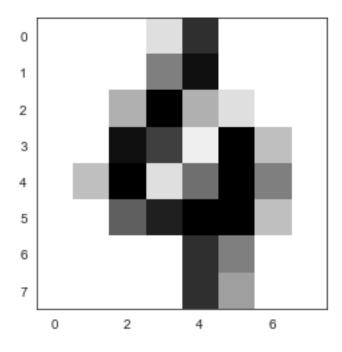

print(digits.images.shape)
  print(digits.data.shape)
```

(1797, 8, 8) (1797, 64)

```
[28]: #Viewing the digits within the dataset.

# The image appears to show a 4 but we can see if the model can predict this plt.imshow(digits.images[100], cmap=plt.cm.gray_r, interpolation='nearest')
```

[28]: <matplotlib.image.AxesImage at 0x16a717c4430>

```
[13]: # Splitting the dataset into test and train sets
      X_train, X_test, y_train, y_test = train_test_split(digits.data, digits.target,_
       →random_state=42)
[36]: # Using the Support Vector Machine (SVM) classifier to classify the digits.
      # First training the classifier on the training set then test it on the
       ⇔testinig set
      # Import the SVM classifier
      from sklearn.svm import SVC
      # Create an SVM classifier
      clf = SVC(gamma='auto')
      # Train the classifier on the training set
      clf.fit(X_train, y_train)
      # Test the classifier on the testing set
      accuracy = clf.score(X_test, y_test)
      print("Test set accuracy: {:.2f}".format(accuracy))
     Test set accuracy: 0.52
[37]: ## Using RandomForest classifier
      from sklearn.ensemble import RandomForestClassifier
      clf = RandomForestClassifier()
      clf.fit(X_train, y_train)
      accuracy = clf.score(X_test, y_test)
      print("Test set accuracy: {:.2f}".format(accuracy))
     Test set accuracy: 0.98
[16]: # Creating the KNN model to use with n equal to 4 (chosen at random by default)
      # General rule for default n is to use odd n if no of variables is even and \Box
      from sklearn.neighbors import KNeighborsClassifier
      knn = KNeighborsClassifier(n_neighbors=4)
      # Fitting the knn model with the feature and target data created previously
      knn.fit(X_train, np.ravel(y_train))
      # getting the predicition values for whole dataset using n=4
```

```
y_pred4 = knn.predict(X_test)

# Check the accuracy score of using n=4
accuracy_score4 = round(metrics.accuracy_score(y_test, y_pred4), 2)
print("Test set accuracy: {:.2f}".format(accuracy_score4))
```

Test set accuracy: 0.99

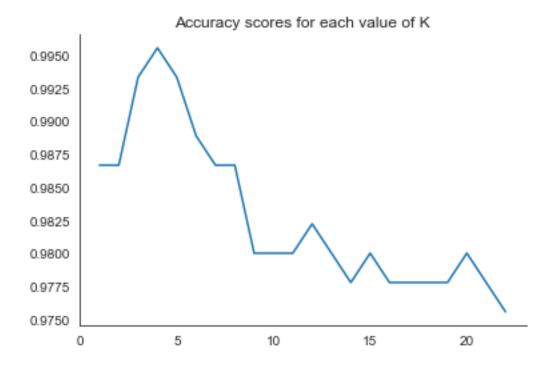

We can see in these two examples that the KNN model is much superior than the SVM and RandomForest by a significant margin

```
[17]: #Tuning the KNN model to find best k value

k_range = range(3, 25)

accuracy_scores = []

for k in k_range:
    knn = KNeighborsClassifier(n_neighbors = k)
    knn.fit(X_train, np.ravel(y_train))
    y_pred = knn.predict(X_test)
    accuracy = metrics.accuracy_score(y_test, y_pred)
    accuracy_scores.append(accuracy)
```

```
[18]: print("The best value of K seems to be", accuracy_scores.

index(max(accuracy_scores))+1)
```

The best value of K seems to be 4

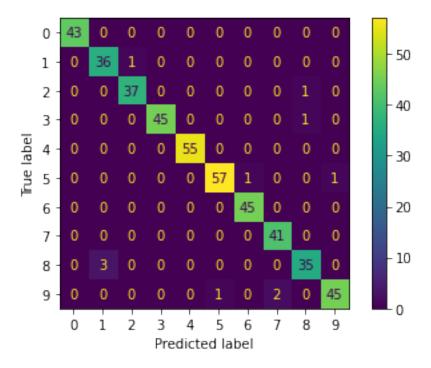

Given we used the value of 4 in our KNN model earlier this doesnt need to change.

```
[19]: # Evaluating the model
## Running a confustion matrix on the knn model.

metrics.plot_confusion_matrix(knn, X_test, y_test);

CM = metrics.confusion_matrix(y_test, y_pred)
```

C:\Users\Dylan\AppData\Local\Programs\Python\Python310\lib\sitepackages\sklearn\utils\deprecation.py:87: FutureWarning: Function
plot\_confusion\_matrix is deprecated; Function `plot\_confusion\_matrix` is
deprecated in 1.0 and will be removed in 1.2. Use one of the class methods:
ConfusionMatrixDisplay.from\_predictions or
ConfusionMatrixDisplay.from\_estimator.
 warnings.warn(msg, category=FutureWarning)

We can see from the above confusion matrix that the digits were more or less correctly predicted with very few outliers. This is a model we can rely upon especially given its 99% accuracy rate.

```
[25]: # Verification of the model using a classification report

print(
    f"Classification report for {knn}:\n"
    f"{metrics.classification_report(y_test, y_pred4)}:\n")
```

The F1 scores for this model is optimal giving it is very close to 1. In addition to the f1 score we can see that the precision and recall scores and similar particularly for where n classifiers is 4, which is what was used in the model, this indicates that there are not so many false positives and false negatives in the model predictions
